Relative abundance/%	100	95	7	5

6.3.2 Quantitation determination

Use the standard working solutions based on estimating the concentration of analyses in the sample.

The responses of analyses in the standard working solution and sample solutions should be within the linear range of the instrumental detection. The standard working solution should be randomly injected in-between the injections of the sample solution of equal volume, and quantitation by external standard. Under the above operating condition, the ethylene dibromide retention time is about 5.9 min. The total ion current chromatograms of ethylene dibromide are in annex B.1. Determinating the standard working solutions and sample solutions based on condition on section 6.3.1. If the retention time of the analyses are the same to that of the external standards when subtraction the background, in the same time the ion relative abundance of the compounds from samples are similar to that of the standards' at the deviation as table 2, it can be inferred that is positive sample.
